WHITE PAPER

The Reef-King Defense & 6/7 Living Monolith

Lead Engineer: Thomas Joseph William Salmon

System Type: Self-Assembling Biogenic Infrastructure (SABI)

Classification: Coastal Defense / Environmental Reinforcement

1.0 ABSTRACT

Conventional coastal defense systems often fail due to static structural fatigue and environmental degradation. The Reef-King Defense system introduces a paradigm shift through the '6/7 Living Monolith' architecture. By integrating bio-receptive materials with a self-healing coral matrix, this system creates a dynamic, biogenic shield that strengthens over time while maintaining ecological equilibrium.

2.0 ARCHITECTURAL SPECIFICATIONS

The core unit consists of the Living Monolith, defined by two critical spatial parameters:

1. The 6ft Concrete Crown: A suspended, high-density bio-receptive concrete cap that serves as the 'seed' for the primary reef colony. It provides the initial mechanical resistance against wave energy.

2. The 7ft Clearance: A deliberate fluid-passage void located beneath the crown. This clearance ensures laminar flow, preventing the 'seawall effect' (backwash erosion) and allowing for nutrient-rich water to reach the lower tiers of the biogenic matrix.

3.0 SELF-ASSEMBLING BIOGENIC INFRASTRUCTURE

The SABI process utilizes a proprietary mix of bio-catalysts embedded within the concrete. Upon deployment, these catalysts trigger rapid aragonite deposition. The resulting coral matrix acts as a self-healing 'skin.' If structural micro-fissures occur during surge events, the biological components bridge the gap through natural calcification, effectively 'fixing' the reef autonomously.

4.0 HYDRODYNAMIC PERFORMANCE

Unlike vertical seawalls that reflect energy (causing sediment scouring), the Reef-King array dissipates

energy through its porous biogenic structure. The 7ft clearance allows tidal surges to pass through the lower structure, while the 6ft crown breaks the cresting force of the wave. This dual-action approach significantly reduces the kinetic impact on the shoreline.

5.0 DATA & SECURITY ARCHITECTURE

System integrity is monitored via G-SHIELD IPFS anchors. These decentralized nodes log structural health and environmental flux without relying on vulnerable centralized servers. This ensures the Reef-King line is not only a physical defense but a secured data network.

6.0 CONCLUSION

The Reef-King Defense represents the next evolution in coastal engineering. It is a transition from 'fighting' the ocean to 'collaborating' with it. Through the 6/7 Living Monolith, coastal regions gain a permanent, self-sustaining defense that grows stronger with every passing season.

PROJECT DESCRIPTION
Reef-King Coastal Defense: The 6/7 Living Monolith – Self-Assembling Biogenic Infrastructure (SABI) for Sustainable Coastal Resilience and Marine Habitat Restoration
